# The Net Part 3

# Addressing on the Layers On The Internet

#### Computer Science 161

#### Weaver

- Ethernet:
  - Address is 6B MAC address, Identifies a machine on the local LAN

#### • IP:

• Address is a 4B (IPv4) or 16B (IPv6) address, Identifies a system on the Internet

#### • TCP/UDP:

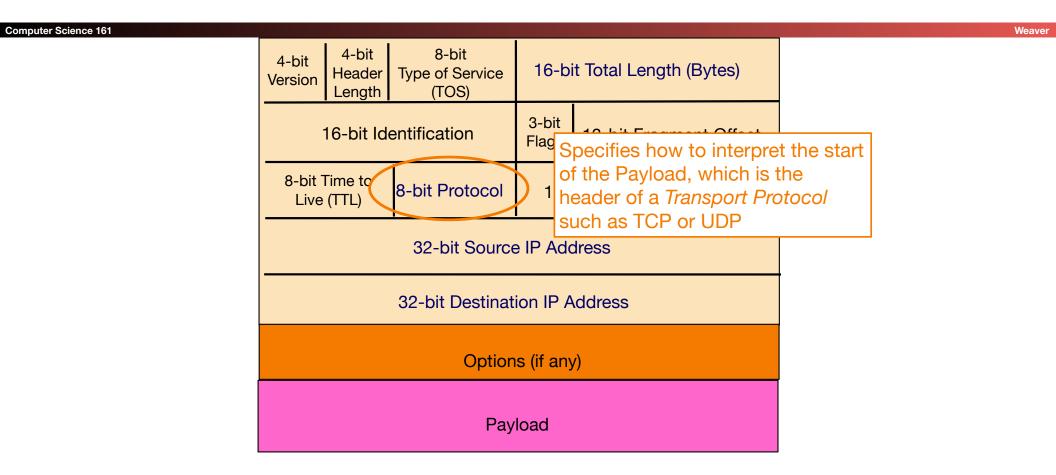

- Address is a 2B port number, Identifies a particular listening server/process/activity on the system
  - Both the client and server have to have a port associated with the communication
- Ports 0-1024 are for privileged services
- Must be root to accept incoming connections on these ports
- Any thing can do an outbound request to such a port
- Port 1025+ are for anybody
  - And high ports are often used ephemerally

Computer Science 161

4-bit Version Length	8-bit Type of Service (TOS)	16-bit Total Length (Bytes)				
16-bit Ide	16-bit Identification		13-bit Fragment Offset

Weaver

### IP Packet Header (Continued)

- Two IP addresses
  - Source IP address (32 bits)
  - Destination IP address (32 bits)
- Destination address
  - Unique identifier/locator for the receiving host
  - Allows each node to make forwarding decisions
- Source address
  - Unique identifier/locator for the sending host
  - Recipient can decide whether to accept packet
  - Enables recipient to send a reply back to source
- Checksum is arithmetic, not CRC...
  - To allow easily modification of the packet by the network

### IP: "Best Effort " Packet Delivery

- Routers inspect destination address, locate "next hop" in forwarding table
  - Address = ~unique identifier/locator for the receiving host
- Only provides a "I'll give it a try" delivery service:
- Packets may be lost
- Packets may be corrupted (but that is 'assume drop' based on layer 2 error detection)

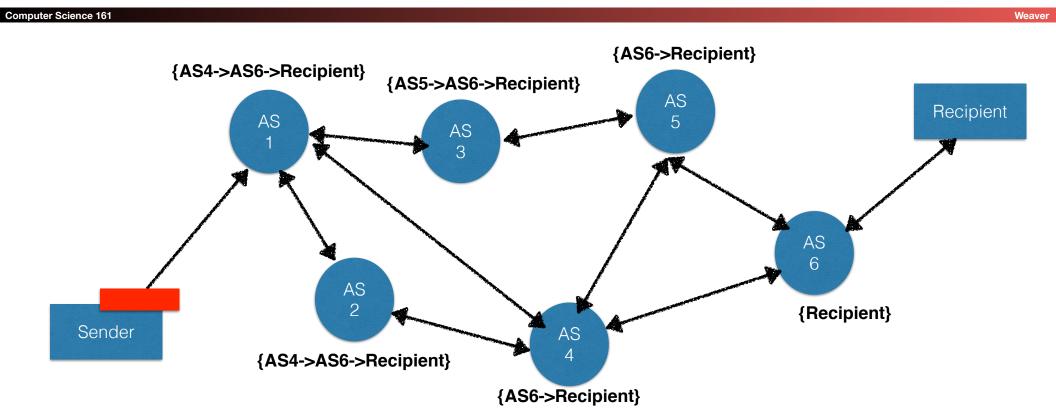

# IP Routing: Autonomous Systems

- Your system sends IP packets to the gateway...
  - But what happens after that?
- Within a given network its routed internally
  - Identified by its ASN (Autonomous System Number)
- But the key is the Internet is a network-of-networks
  - Each "autonomous system" (AS) handles its own internal routing
  - The AS knows the next AS to forward a packet to
- Primary protocol for communicating in between ASs is BGP:
  - Each router announces what networks it can provide and the path onward
  - Most precise route with the shortest path and no loops preferred

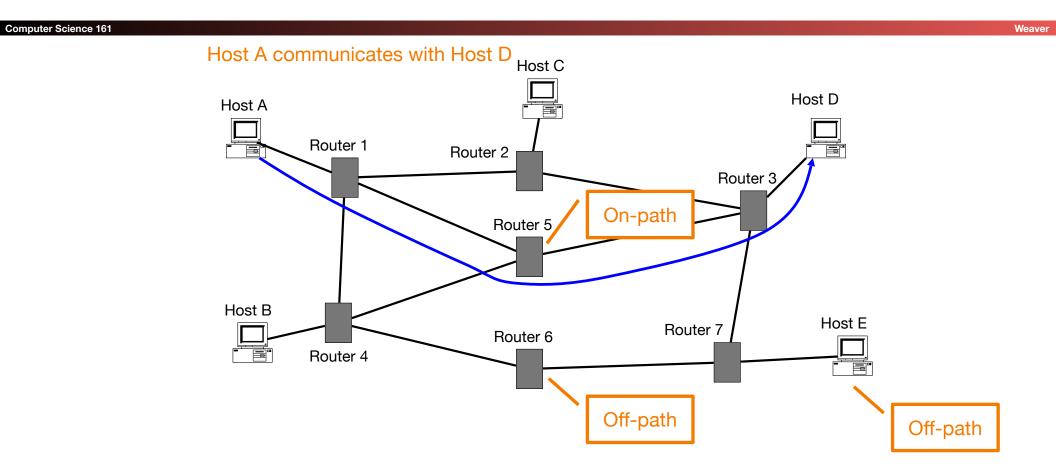

# Packet Routing on the Internet: Border Gateway Protocol & Routing Tables

# IP Spoofing And Autonomous Systems

- Weav
- The edge-AS where a user connects should restrict packet spoofing
- Sending a packet with a different sender IP address
- But about 25% of them don't...
  - So a system can simply lie and say it comes from someplace else
- This enables blind-spoofing attacks
  - Such as the Kaminski attack on DNS which we will see in a second
- It also enables "reflected DOS attacks"
  - Send a small request...
     That sends a large reply...
     To the fake "sender" of the packet

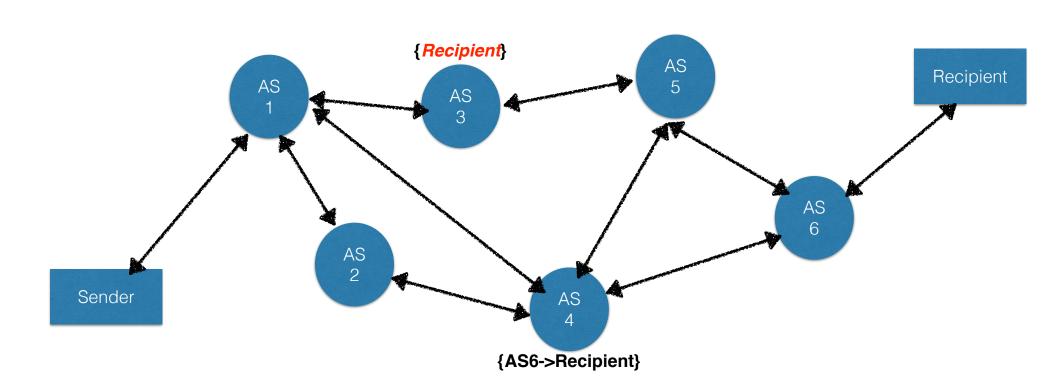

### **On-path Injection vs Off-path Spoofing**

# Lying in BGP

**Computer Science 161** 

Weaver

# UDP: Datagrams on the Internet

- UDP is a protocol built on the Internet Protocol (IP)
- It is an "unreliable, datagram protocol"
  - Messages may or may not be delivered, in any order
  - Messages can be larger than a single packet (but probably shouldn't)
    - IP will fragment these into multiple packets (mostly... Single digit %-age of hosts can't receive fragmented traffic)

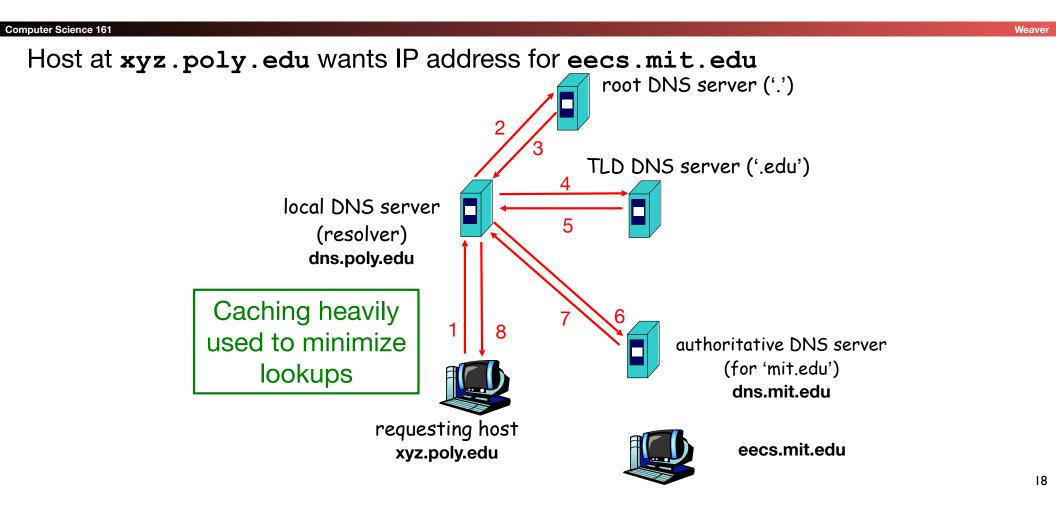

#### Programs create a socket to send and receive messages

- Just create a datagram socket for an ephemeral port
- Bind the socket to a particular port to receive traffic on a specified port
- Basic recipe for Python: <u>https://wiki.python.org/moin/UdpCommunication</u>

# **DNS** Overview

- DNS translates www.google.com to 74.125.25.99
  - Turns a human abstraction into an IP address
  - Can also contain other data
- It's a performance-critical distributed database.
- DNS security is critical for the web.
   (Same-origin policy *assumes* DNS is secure.)
  - Analogy: If you don't know the answer to a question, ask a friend for help (who
    may in turn refer you to a friend of theirs, and so on).
- Based on a notion of hierarchical trust:
  - You trust . for everything, com. for any com, google.com. for everything google...

### DNS Lookups via a Resolver

### Security risk #1: malicious DNS server

- Of course, if any of the DNS servers queried are malicious, they can lie to us and fool us about the answer to our DNS query
- (In fact, they used to be able to fool us about the answer to other queries, too. We'll come back to that.)

### Security risk #2: on-path eavesdropper

#### Computer Science 161

Weaver

- If attacker can eavesdrop on our traffic... we're hosed.
- Why? We'll see why.

### Security risk #3: off-path attacker

- If attacker can't eavesdrop on our traffic, can he inject spoofed DNS responses?
- This case is especially interesting, so we'll look at it in detail.

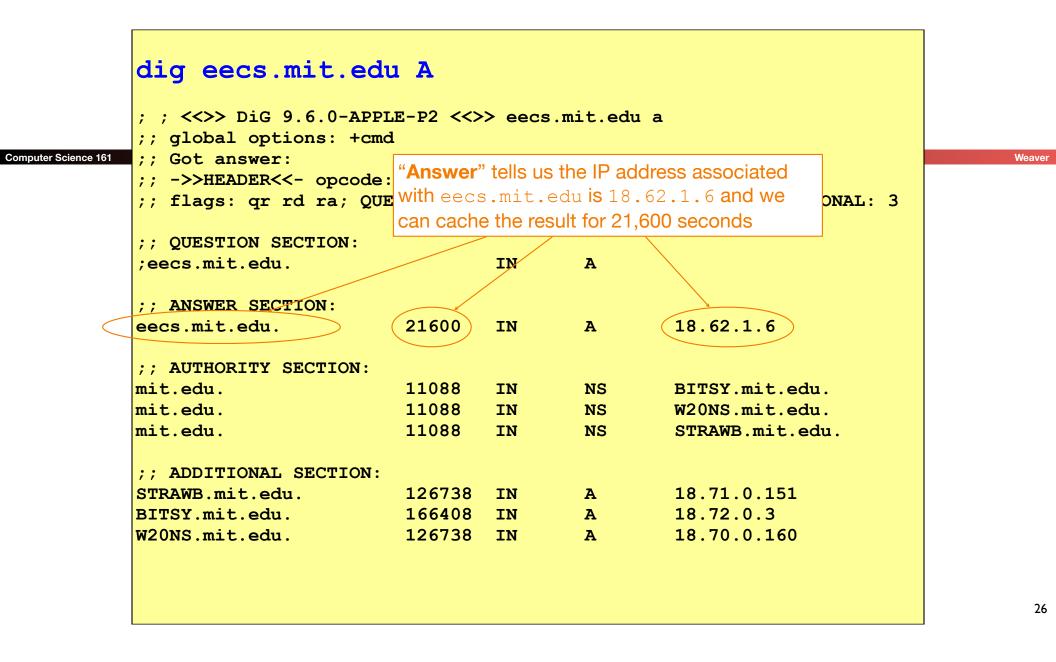

### **DNS** Threats

- DNS: path-critical for just about everything we do
  - Maps hostnames ↔ IP addresses
  - Design only scales if we can minimize lookup traffic
    - #1 way to do so: caching
    - #2 way to do so: return not only answers to queries, but additional info that will likely be needed shortly
      - The "glue records"
- What if attacker eavesdrops on our DNS queries?
  - Then similar to DHCP, ARP, AirPwn etc, can spoof responses
- Consider attackers who can't eavesdrop but still aim to manipulate us via how the protocol functions
- Directly interacting w/ DNS: dig program on Unix
  - Allows querying of DNS system
  - Dumps each field in DNS responses

### **DNS Resource Records and RRSETs**

- DNS records (Resource Records) can be one of various types
  - Name TYPE Value
    - · Also a "time to live" field: how long in seconds this entry can be cached for
  - Addressing:
    - A: IPv4 addresses
    - AAAA: IPv6 addresses
    - CNAME: aliases, "Name X should be name Y"
    - MX: "the mailserver for this name is Y"
  - DNS related:
    - NS: "The authority server you should contact is named Y"
    - SOA: "The operator of this domain is Y"
  - Other:
    - text records, cryptographic information, etc....
- Groups of records of the same type form RRSETs:
  - E.g. all the nameservers for a given domain.

  - dig +norecurse www.isc.org @199.6.1.30

### Security risk #1: malicious DNS server

- Of course, if any of the DNS servers queried are malicious, they can lie to us and fool us about the answer to our DNS query...
- and they used to be able to fool us about the answer to other queries, too, using *cache poisoning*. Now fixed (phew).

### Security risk #2: on-path eavesdropper

#### Computer Science 161

- If attacker can eavesdrop on our traffic... we're hosed.
- Why?

### Security risk #2: on-path eavesdropper

- If attacker can eavesdrop on our traffic... we're hosed.
- Why? They can see the query and the 16-bit transaction identifier, and race to send a spoofed response to our query.
  - China does this operationally:
  - dig www.benign.com @www.tsinghua.edu.cn
  - dig www.facebook.com @www.tsinghua.edu.cn

### Security risk #3: off-path attacker

```
Weaver
```

- If attacker can't eavesdrop on our traffic, can he inject spoofed DNS responses?
- Answer: It used to be possible, via *blind spoofing*.
   We've since deployed mitigations that makes this harder (but not totally impossible).

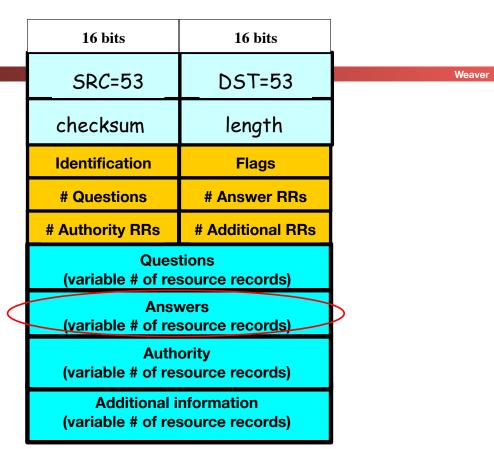

# Blind spoofing

**Computer Science 161** 

- Say we look up mail.google.com; how can an off-path attacker feed us a bogus A answer before the legitimate server replies?
- How can such a **remote** attacker even know we are looking up mail.google.com?

Suppose, e.g., we visit a web page under their control:

...<img src="http://mail.google.com" ...> ...

...<img src="http://mail.google.com" ...> ...

leaver

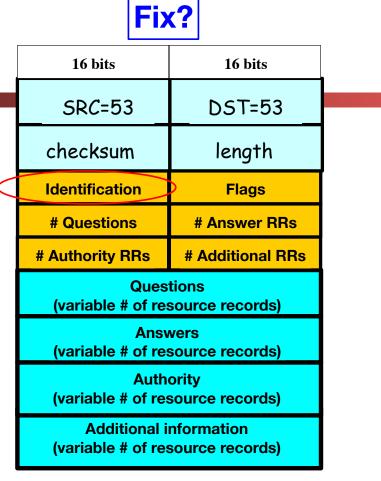

# Blind spoofing

#### Computer Science 161

Once they know we're looking it up, they just have to guess the Identification field and reply before legit server.

How hard is that?

Originally, identification field incremented by 1 for each request. How does attacker guess it?

<img src="http://badguy.com" ...> They observe ID k here <img src="http://mail.google.com" ...> So this will be k+1

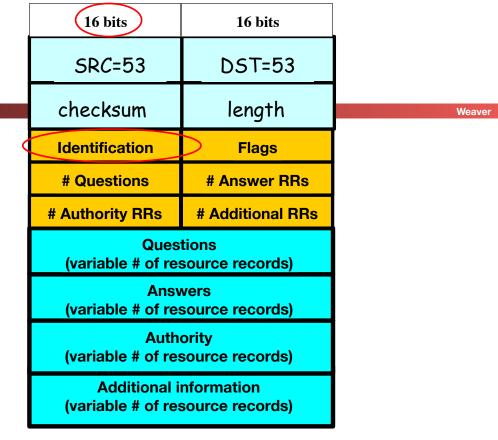

### DNS Blind Spoofing, cont.

#### Computer Science 161

Once we randomize the Identification, attacker has a 1/65536 chance of guessing it correctly. Are we pretty much safe?

Attacker can send lots of replies, not just one ...

However: once reply from legit server arrives (with correct Identification), it's **cached** and no more opportunity to poison it. Victim is innoculated!

Unless attacker can send 1000s of replies before legit arrives, we're likely safe – phew! **?** 

# Enter Kaminski... Glue Attacks

Com	puter	Sci	ence	161	

- Dan Kaminski noticed something strange, however...
  - Most DNS servers would cache the in-bailiwick glue...
  - And then *promote* the glue
  - And will also *update* entries based on glue
- So if you first did this lookup...
  - And then went to query for a0.org.afilias-nst.info
  - there would be no other lookup!

<pre>nweaver% dig +norecurse slashdot.org @a.root-servers.net</pre>

## The Kaminski Attack In Practice

- Rather than trying to poison www.google.com...
- Instead try to poison a.google.com...
   And state that "www.google.com" is an authority
   And state that "www.google.com A 133.7.133.7"
  - If you succeed, great!
- But if you fail, just try again with b.google.com!
  - Turns "Race once per timeout" to "race until win"
- So now the attacker may still have to send lots of packets
  - In the 10s of thousands
- The attacker can keep trying until success

# Defending Against Kaminski: Up the Entropy

- Computer Science 161
  - Also randomize the UDP source port
    - Adds ~16 bits of entropy
  - Observe that most DNS servers just copy the request directly
    - Rather than create a new reply
  - So caMeLcase the NamE ranDomly
    - Adds only a few bits of entropy however, but it does help

## Defend Against Kaminski: Validate Glue

- Computer Science 161
  - Don't blindly accept glue records...
    - Well, you *have* to accept them for the purposes of resolving a name
  - But if you are going to cache the glue record...
  - Either only use it for the context of a DNS lookup
  - No more promotion
  - Or explicitly validate it with another fetch
  - Unbound implemented this, bind did not
    - Largely a *political* decision: bind's developers are heavily committed to DNSSEC (an upcoming topic)

# Oh, and Profiting from Rogue DNS

- Suppose you take over a lot of home routers...
  - How do you make money with it?
- Simple: Change their DNS server settings
  - Make it point to yours instead of the ISPs
- Now redirect all advertising
  - And instead serve up ads for "Vimax" pills...
- Can only do this for unencrypted sites, but....
