

# Pseudorandom generator (PRG)

# Pseudorandom Generator (PRG)

- Given a seed, it outputs a sequence of random bits

$\text{PRG}(\text{seed}) \rightarrow \text{random bits}$

- It can output arbitrarily many random bits

# PRG security

- Can  $\text{PRG}(K)$  be truly random?

No. Consider key length  $|K|=k$ . Have  $2^k$  possible initial states of PRG. Deterministic from then on. There are more random states.

- A secure PRG suffices to “look” random (“pseudo”) to an attacker (no attacker can distinguish it from a random sequence)

# Example of PRG: using block cipher in CTR mode

If you want  $m$  random bits, and a block cipher with  $E_k$  has  $n$  bits, apply the block cipher  $m/n$  times and concatenate the result:

$$\text{PRG}(K \mid IV) = E_k(IV \mid 1) \mid E_k(IV \mid 2) \mid E_k(IV \mid 3) \\ \dots E_k(IV \mid \text{ceil}(m/n)), \quad \text{where } \mid \text{ is concatenation}$$

# Application of PRG: Stream ciphers

- Another way to construct encryption schemes
- Similar in spirit to one-time pad: it XORs the plaintext with some random bits
- But random bits are not the key (as in one-time pad) but are output of a pseudorandom generator PRG

# Application of PRG: Stream cipher

Enc(K, M):

- Choose a random value IV
- $C = \text{PRG}(K \mid \text{IV}) \text{ XOR } M$
- Output (IV, C)

Q: How decrypt?

A: Compute  $\text{PRG}(K \mid \text{IV})$  and XOR with ciphertext C

Q: What is advantage over OTP?

A: Can encrypt any message length because PRG can produce any number of random bits, and multiple times because IV is chosen at random in Enc
